# Fix for article editor removing a script

Last modified on 10/01/2026 3:56 pm EDT

The article editor does its best to ensure that you have valid HTML in your article. Unfortunately, sometimes it can be a little heavy-handed with how it interprets "valid" HTML. Sometimes, it can remove a custom script you've added.

We've seen this happen most often with scripts that use their own HTML tags, such as:

- Tableau
- Redocly

As a workaround to this issue, add the script into a snippet and insert the snippet into the article following these instructions:

1. Create a snippet to put the script into.
2. As you create the snippet, select the **Snippet Content** dropdown and select **Code Editor**:
   Your browser does not support HTML5 video.
3. Paste your script in.
4. Keep the snippet in **Code Editor** whenever you open it. This particular Code Editor bypasses all of the HTML-cleaning functions that the WYSIWYG Editor has, so your script will stay whole and functional.
5. Once you've finished creating the snippet, insert that snippet into any article where you need the script to run.

You can see more how to set this up in our Wisdom Wednesday recording on the topic (this particular solution is the third and final use case discussed in that video!)
