

Fix for article editor removing a script

Last Modified on 12/22/2025 3:40 pm EST

The article editor does its best to ensure that you have valid HTML in your article. Unfortunately, sometimes it can be a little heavy-handed with how it interprets "valid" HTML. Sometimes, it can remove a custom script you've added.

We've seen this happen most often with scripts that use their own HTML tags, such as:

- Tableau
- Redocly

As a workaround to this issue, you can:

1. [Create a snippet](#) to put the script into.
2. As you create the snippet, select the **Snippet Content** dropdown and select **Code Editor**:
Your browser does not support HTML5 video.
3. Paste your script in.
4. Keep the snippet in **Code Editor** whenever you open it. This particular Code Editor bypasses all of the HTML-cleaning functions that the WYSIWYG Editor has, so your script will stay whole and functional.
5. Once you've finished creating the snippet, you can [insert that snippet](#) into any article where you need the script to run.

You can see more how to set this up in our [Wisdom Wednesday recording on the topic](#) (this particular solution is the third and final use case discussed in that video!)
